Eigenvectors and Eigenvalues

Definition

Let A be an $n \times n$ matrix.

1. An **eigenvector** of A is a nonzero vector v in \mathbf{R}^n such that $Av = \lambda v$, for some λ in \mathbf{R} . In other words, Av is a multiple of v .
2. An **eigenvalue** of A is a number λ in \mathbf{R} such that the equation $Av = \lambda v$ has a nontrivial solution.

If $Av = \lambda v$ for $v \neq 0$, we say λ is the **eigenvalue for** v , and v is an **eigenvector for** λ .

Definition

Let A be an $n \times n$ matrix and let λ be an eigenvalue of A . The λ -**eigenspace** of A is the set of all eigenvectors of A with eigenvalue λ , plus the zero vector:

$$\begin{aligned}\lambda\text{-eigenspace} &= \{v \text{ in } \mathbf{R}^n \mid Av = \lambda v\} \\ &= \{v \text{ in } \mathbf{R}^n \mid (A - \lambda I)v = 0\} \\ &= \text{Nul}(A - \lambda I).\end{aligned}$$

You find a basis for the λ -eigenspace by finding the parametric vector form for the general solution to $(A - \lambda I)x = 0$ using row reduction.

The Characteristic Polynomial

Definition

Let A be an $n \times n$ matrix. The **characteristic polynomial** of A is

$$f(\lambda) = \det(A - \lambda I).$$

Important Facts:

1. The characteristic polynomial is a polynomial of degree n , of the following form:

$$f(\lambda) = (-1)^n \lambda^n + a_{n-1} \lambda^{n-1} + a_{n-2} \lambda^{n-2} + \cdots + a_1 \lambda + a_0.$$

2. The eigenvalues of A are the roots of $f(\lambda)$.
3. The constant term $f(0) = a_0$ is equal to $\det(A)$:

$$f(0) = \det(A - 0I) = \det(A).$$

4. The characteristic polynomial of a 2×2 matrix A is

$$f(\lambda) = \lambda^2 - \text{Tr}(A) \lambda + \det(A).$$

Definition

The **algebraic multiplicity** of an eigenvalue λ is its multiplicity as a root of the characteristic polynomial.

Similarity

Definition

Two $n \times n$ matrices A and B are **similar** if there is an invertible $n \times n$ matrix P such that

$$A = PBP^{-1}.$$

Important Facts:

1. Similar matrices have the same characteristic polynomial.
2. It follows that similar matrices have the same eigenvalues.
3. If A is similar to B and B is similar to C , then A is similar to C .

Caveats:

1. Matrices with the same characteristic polynomial need not be similar.
2. Similarity has nothing to do with row equivalence.
3. Similar matrices usually do not have the same eigenvectors.

Similarity

Geometric meaning

Let $A = PBP^{-1}$, and let v_1, v_2, \dots, v_n be the columns of P . These form a basis \mathcal{B} for \mathbf{R}^n because P is invertible. *Key relation:* for any vector x in \mathbf{R}^n ,

$$[Ax]_{\mathcal{B}} = B[x]_{\mathcal{B}}.$$

This says:

A acts on the usual coordinates of x
in the same way that
 B acts on the \mathcal{B} -coordinates of x .

Example:

$$A = \frac{1}{4} \begin{pmatrix} 5 & 3 \\ 3 & 5 \end{pmatrix} \quad B = \begin{pmatrix} 2 & 0 \\ 0 & 1/2 \end{pmatrix} \quad P = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.$$

Then $A = PBP^{-1}$. B acts on the usual coordinates by scaling the first coordinate by 2, and the second by $1/2$:

$$B \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 2x_1 \\ x_2/2 \end{pmatrix}.$$

The unit coordinate vectors are eigenvectors: e_1 has eigenvalue 2, and e_2 has eigenvalue $1/2$.

Similarity

Example

$$A = \frac{1}{4} \begin{pmatrix} 5 & 3 \\ 3 & 5 \end{pmatrix} \quad B = \begin{pmatrix} 2 & 0 \\ 0 & 1/2 \end{pmatrix} \quad P = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \quad [Ax]_{\mathcal{B}} = B[x]_{\mathcal{B}}.$$

In this case, $\mathcal{B} = \left\{ \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ -1 \end{pmatrix} \right\}$. Let $v_1 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ and $v_2 = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$.

To compute $y = Ax$:

Say $x = \begin{pmatrix} 2 \\ 0 \end{pmatrix}$.

1. Find $[x]_{\mathcal{B}}$.

1. $x = v_1 + v_2$ so $[x]_{\mathcal{B}} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$.

2. $[y]_{\mathcal{B}} = B[x]_{\mathcal{B}}$.

2. $[y]_{\mathcal{B}} = B \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 2 \\ 1/2 \end{pmatrix}$.

3. Compute y from $[y]_{\mathcal{B}}$.

3. $y = 2v_1 + \frac{1}{2}v_2 = \begin{pmatrix} 5/2 \\ 3/2 \end{pmatrix}$.

Picture:

Diagonalization

Definition

An $n \times n$ matrix A is **diagonalizable** if it is similar to a diagonal matrix:

$$A = PDP^{-1} \quad \text{for } D \text{ diagonal.}$$

It is easy to take powers of diagonalizable matrices:

$$A^n = PD^nP^{-1}.$$

The Diagonalization Theorem

An $n \times n$ matrix A is diagonalizable if and only if A has n linearly independent eigenvectors. In this case, $A = PDP^{-1}$ for

$$P = \begin{pmatrix} | & | & \cdots & | \\ v_1 & v_2 & \cdots & v_n \\ | & | & \cdots & | \end{pmatrix} \quad D = \begin{pmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_n \end{pmatrix},$$

where v_1, v_2, \dots, v_n are linearly independent eigenvectors, and $\lambda_1, \lambda_2, \dots, \lambda_n$ are the corresponding eigenvalues (in the same order).

Corollary

An $n \times n$ matrix with n distinct eigenvalues is diagonalizable.

Non-Distinct Eigenvalues

Definition

Let A be a square matrix with eigenvalue λ . The **geometric multiplicity** of λ is the dimension of the λ -eigenspace.

Theorem

Let A be an $n \times n$ matrix. Then A is diagonalizable if and only if, for every eigenvalue λ , the algebraic multiplicity of λ is equal to the geometric multiplicity.

(And all eigenvalues are real, unless you want to diagonalize over \mathbf{C} .)

Notes:

- ▶ The algebraic and geometric multiplicities are both whole numbers ≥ 1 , and the algebraic multiplicity is always greater than or equal to the geometric multiplicity. In particular, they're equal if the algebraic multiplicity is 1.
- ▶ Equivalently, A is diagonalizable if and only if the sum of the geometric multiplicities of its eigenvalues is n .

Non-Distinct Eigenvalues

Example

$$A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix}$$

This has eigenvalues 1 and 2, with algebraic multiplicities 2 and 1, respectively.

The geometric multiplicity of 2 is *automatically* 1.

Let's compute the geometric multiplicity of 1:

$$A - I = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \xrightarrow{\text{rref}} \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}.$$

This has 1 free variable, so the geometric multiplicity of 1 is 1. This is less than the algebraic multiplicity, so the matrix is *not diagonalizable*.

Stochastic Matrices

Definition

A square matrix A is **stochastic** if all of its entries are nonnegative, and the sum of the entries of each column is 1. It A is **positive** if all of its entries are positive.

Definition

A *steady state* for a stochastic matrix A is an eigenvector w with eigenvalue 1, such that its entries are positive and sum to 1.

Perron–Frobenius Theorem

If A is a positive stochastic matrix, then it admits a unique steady state vector w , which spans the 1-eigenspace.

Moreover, for any vector v_0 with entries summing to some number c , the iterates $v_1 = Av_0$, $v_2 = Av_1$, \dots , $v_n = Av_{n-1}$, \dots , approach cw as n gets large.

Think about it in terms of Red Box movies: v_n is the number of movies in each location on day n , and $v_{n+1} = Av_n$. Eventually, the number of movies in each location will be the same every day: $v_n = v_{n+1} = Av_n$. This means v_n is an eigenvector with eigenvalue 1, so it is a multiple of the steady state w : $v_n = cw$. The steady state w tells you the *percentages* of movies that are in each location, so c is the total number of movies. So if you started with $c = 100$ movies on day 0, then you know $v_n = cw = 100w$ for large enough n : the total number of movies doesn't change.

Computing the Steady State

$$A = \begin{pmatrix} .3 & .4 & .5 \\ .3 & .4 & .3 \\ .4 & .2 & .2 \end{pmatrix}$$

This is a positive stochastic matrix. To compute the steady state, first we find *some* eigenvector with eigenvalue 1:

$$A - I = \begin{pmatrix} -.7 & .4 & .5 \\ .3 & -.6 & .3 \\ .4 & .2 & -.8 \end{pmatrix} \xrightarrow{\text{rref}} \begin{pmatrix} 1 & 0 & -7/5 \\ 0 & 1 & -6/5 \\ 0 & 0 & 0 \end{pmatrix}.$$

The parametric vector form is $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = z \begin{pmatrix} 7/5 \\ 6/5 \\ 1 \end{pmatrix}$, so an eigenvector is $\begin{pmatrix} 7 \\ 6 \\ 5 \end{pmatrix}$.

We want the entries of our eigenvector to sum to 1, so we need to divide by the sum of the entries:

$$w = \frac{1}{7 + 6 + 5} \begin{pmatrix} 7 \\ 6 \\ 5 \end{pmatrix} = \frac{1}{18} \begin{pmatrix} 7 \\ 6 \\ 5 \end{pmatrix}.$$

This is the steady state. If $v = (6, 22, 8)$ then $A^n v$ approaches $36w = (14, 12, 10)$.

Complex Eigenvectors

Complex eigenvalues and eigenvectors work just like their real counterparts, with the additional fact:

Both eigenvalues and eigenvectors of real square matrices occur in conjugate pairs.

Example: $A = \begin{pmatrix} \sqrt{3} + 1 & -2 \\ 1 & \sqrt{3} - 1 \end{pmatrix}$. The characteristic polynomial is

$$f(\lambda) = \lambda^2 - \operatorname{Tr}(A)\lambda + \det(A) = \lambda^2 - 2\sqrt{3}\lambda + 4.$$

The quadratic formula tells us the eigenvalues are

$$\lambda = \frac{2\sqrt{3} \pm \sqrt{(2\sqrt{3})^2 - 16}}{2} = \sqrt{3} \pm i.$$

Let's compute an eigenvector v with eigenvalue $\lambda = \sqrt{3} - i$.

$$A - \lambda I = \begin{pmatrix} 1+i & -2 \\ \star & \star \end{pmatrix} \rightsquigarrow v = \begin{pmatrix} 2 \\ 1+i \end{pmatrix}.$$

An eigenvector with eigenvalue $\sqrt{3} + i$ is (automatically) $\begin{pmatrix} 2 \\ 1-i \end{pmatrix}$.

Geometric Interpretation of Complex Eigenvalues

Theorem

Let A be a 2×2 matrix with complex (non-real) eigenvalue λ , and let v be an eigenvector. Then

$$A = PCP^{-1}$$

where

$$P = \begin{pmatrix} | & | \\ \text{Re } v & \text{Im } v \\ | & | \end{pmatrix} \quad \text{and} \quad C = \begin{pmatrix} \text{Re } \lambda & \text{Im } \lambda \\ -\text{Im } \lambda & \text{Re } \lambda \end{pmatrix}.$$

The matrix C is a composition of a counterclockwise rotation by $-\arg(\lambda)$, and a scale by a factor of $|\lambda|$.

Example:

$$A = \begin{pmatrix} \sqrt{3} + 1 & -2 \\ 1 & \sqrt{3} - 1 \end{pmatrix} \quad \lambda = \sqrt{3} - i \quad v = \begin{pmatrix} 1 - i \\ 1 \end{pmatrix}$$

This gives

$$C = \begin{pmatrix} \text{Re } \lambda & \text{Im } \lambda \\ -\text{Im } \lambda & \text{Re } \lambda \end{pmatrix} = \begin{pmatrix} \sqrt{3} & -1 \\ 1 & \sqrt{3} \end{pmatrix}$$
$$P = \begin{pmatrix} \text{Re}(1 - i) & \text{Im}(1 - i) \\ \text{Re}(1) & \text{Im}(1) \end{pmatrix} = \begin{pmatrix} 1 & -1 \\ 1 & 0 \end{pmatrix}$$

Geometric Interpretation of Complex Eigenvalues

Example

$$A = \begin{pmatrix} \sqrt{3}+1 & -2 \\ 1 & \sqrt{3}-1 \end{pmatrix} \quad C = \begin{pmatrix} \sqrt{3} & -1 \\ 1 & \sqrt{3} \end{pmatrix} \quad P = \begin{pmatrix} 1 & -1 \\ 1 & 0 \end{pmatrix} \quad \lambda = \sqrt{3}-i$$

The Theorem says that C scales by a factor of

$$|\lambda| = \sqrt{(\sqrt{3})^2 + (-1)^2} = \sqrt{3+1} = 2.$$

It rotates counterclockwise by the argument of $\bar{\lambda} = \sqrt{3} + i$, which is $\pi/6$:

Computing the Argument of a Complex Number

Caveat

Warning: if $\lambda = a + bi$, you can't just plug $\tan^{-1}(b/a)$ into your calculator and expect to get the argument of λ .

Example: If $\lambda = -1 - \sqrt{3}i$ then

$$\tan^{-1}\left(\frac{-\sqrt{3}}{-1}\right) = \tan^{-1}(\sqrt{3}) = \frac{\pi}{3}.$$

Anyway that's the number your calculator will give you.

You have to *draw a picture*:

$$\theta = \tan^{-1}(\sqrt{3}) = \frac{\pi}{3}$$
$$\text{argument} = \theta + \pi = \frac{4\pi}{3}$$
