Recall: the formula

$$\det(A) = \sum_{j=1}^n a_{1j} C_{1j} = a_{11} C_{11} + a_{12} C_{12} + \cdots + a_{1n} C_{1n}.$$

is called **cofactor expansion along the first row**. Actually, you can expand cofactors along any row or column you like!

$$\det A = \sum_{j=1}^n a_{ij} C_{ij} \quad \text{for any fixed } i$$

$$\det A = \sum_{i=1}^n a_{ij} C_{ij} \quad \text{for any fixed } j$$

Try this with a row or a column with a lot of zeros.

The Determinant of an Upper-Triangular Matrix

The Determinant of an Upper-Triangular Matrix

The computation in the proof only uses that the matrix is *upper-triangular* (all entries below the main diagonal are zero).

Theorem

The determinant of an upper-triangular matrix is the product of the diagonal entries:

A Formula for the Inverse

For fun—from §3.3

For 2×2 matrices we had a nice formula for the inverse:

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \implies A^{-1} = \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$$

The proof uses Cramer’s rule. See Dan Margalit’s notes on the website for a nice explanation.
